1 public_key User's Guide

This application provides an API to public-key infrastructure from **RFC 5280** (X.509 certificates) and public-key formats defined by the **PKCS** standard.

1.1 Introduction

1.1.1 Purpose

The Public Key application deals with public-key related file formats, digital signatures, and **X-509 certificates**. It is a library application that provides encode/decode, sign/verify, encrypt/decrypt, and similar functionality. It does not read or write files, it expects or returns file contents or partial file contents as binaries.

1.1.2 Prerequisites

It is assumed that the reader is familiar with the Erlang programming language and has a basic understanding of the concepts of using public-keys and digital certificates.

1.1.3 Performance Tips

The Public Key decode- and encode-functions try to use the NIFs in the ASN.1 compilers runtime modules, if they can be found. Thus, to have the ASN1 application in the path of your system gives the best performance.

1.2 Public-Key Records

This chapter briefly describes Erlang records derived from ASN.1 specifications used to handle public key infrastructure. The scope is to describe the data types of each component, not the semantics. For information on the semantics, refer to the relevant standards and RFCs linked in the sections below.

Use the following include directive to get access to the records and constant macros described in the following sections:

```
-include_lib("public_key/include/public_key.hrl").
```

1.2.1 Data Types

Common non-standard Erlang data types used to describe the record fields in the following sections and which are not defined in the Public Key *Reference Manual* follows here:

```
time() =  
    utc_time() | general_time()  
utc_time() =  
    {utcTime, "YYMMDDHHMMSSZ"}  
general_time() =  
    {generalTime, "YYYYMMDDHHMMSSZ"}  
general_name() =  
    {rfc822Name, string()}
```

```
| {dNSName, string()}
| {x400Address, string()}
| {directoryName, {rdnSequence, [#AttributeTypeAndValue'{}]]}}
| {ediPartyName, special_string()}
| {ediPartyName, special_string(), special_string()}
| {uniformResourceIdentifier, string()}
| {iPAddress, string()}
| {registeredId, oid()}
| {otherName, term()}
special_string() =
    {teletexString, string()}
    | {printableString, string()}
    | {universalString, string()}
    | {utf8String, binary()}
    | {bmpString, string()}
dist_reason() =
    unused
    | keyCompromise
    | cACompromise
    | affiliationChanged
    | superseded
    | cessationOfOperation
    | certificateHold
    | privilegeWithdrawn
    | aACompromise
OID_macro() =
    ?OID_name()
OID_name() =
    atom()
```

1.2.2 RSA

Erlang representation of **Rivest-Shamir-Adleman cryptosystem (RSA)** keys follows:

1.2 Public-Key Records

```
#'RSAPublicKey'{
  modulus,      % integer()
  publicExponent % integer()
  }.

#'RSAPrivateKey'{
  version,      % two-prime | multi
  modulus,      % integer()
  publicExponent % integer()
  privateExponent % integer()
  prime1,       % integer()
  prime2,       % integer()
  exponent1,    % integer()
  exponent2,    % integer()
  coefficient,   % integer()
  otherPrimeInfos % [#OtherPrimeInfo{}] | asn1_NOVALUE
  }.

#'OtherPrimeInfo'{
  prime,      % integer()
  exponent,   % integer()
  coefficient % integer()
  }.
```

1.2.3 DSA

Erlang representation of **Digital Signature Algorithm (DSA)** keys

```
#'DSAPrivateKey',{
  version,      % integer()
  p,           % integer()
  q,           % integer()
  g,           % integer()
  y,           % integer()
  x,           % integer()
  }.

#'Dss-Parms',{
  p,           % integer()
  q,           % integer()
  g,           % integer()
  }.

```

1.2.4 ECDSA

Erlang representation of **Elliptic Curve Digital Signature Algorithm (ECDSA)** keys follows:

```

#'ECPrivateKey'{
    version,          % integer()
    privateKey,       % binary()
    parameters,       % {ecParameters, #'ECParameters' {}} |
                     % {namedCurve, Oid::tuple()} |
                     % {implicitlyCA, 'NULL'}
    publicKey         % bitstring()
}.

#'ECParameters'{
    version,          % integer()
    fieldID,          % #'FieldID' {}
    curve,            % #'Curve' {}
    base,            % binary()
    order,            % integer()
    cofactor         % integer()
}.

#'Curve'{
    a,               % binary()
    b,               % binary()
    seed            % bitstring() - optional
}.

#'FieldID'{
    fieldType,       % oid()
    parameters       % Depending on fieldType
}.

#'ECPoint'{
    point % binary() - the public key
}.

```

1.2.5 PKIX Certificates

Erlang representation of PKIX certificates derived from ASN.1 specifications see also **X509 certificates (RFC 5280)**, also referred to as plain type, are as follows:

```

#'Certificate'{
    tbsCertificate,    % #'TBSCertificate' {}
    signatureAlgorithm, % #'AlgorithmIdentifier' {}
    signature          % bitstring()
}.

#'TBSCertificate'{
    version,          % v1 | v2 | v3
    serialNumber,     % integer()
    signature,        % #'AlgorithmIdentifier' {}
    issuer,           % {rdnSequence, [#AttributeTypeAndValue' {}]}
    validity,         % #'Validity' {}
    subject,          % {rdnSequence, [#AttributeTypeAndValue' {}]}
    subjectPublicKeyInfo, % #'SubjectPublicKeyInfo' {}
    issuerUniqueID,    % binary() | asn1_novalue
    subjectUniqueID,   % binary() | asn1_novalue
    extensions        % [#'Extension' {}]
}.

#'AlgorithmIdentifier'{
    algorithm, % oid()
    parameters % der_encoded()
}.

```

1.2 Public-Key Records

Erlang alternate representation of PKIX certificate, also referred to as otp type

```
#'OTPCertificate'{
  tbsCertificate,      % #'OTPTBSCertificate'{}
  signatureAlgorithm,  % #'SignatureAlgorithm'
  signature             % bitstring()
}.

#'OTPTBSCertificate'{
  version,             % v1 | v2 | v3
  serialNumber,        % integer()
  signature,           % #'SignatureAlgorithm'
  issuer,              % {rdnSequence, [#AttributeTypeAndValue'{}]}
  validity,            % #'Validity'{}
  subject,             % {rdnSequence, [#AttributeTypeAndValue'{}]}
  subjectPublicKeyInfo, % #'OTPSubjectPublicKeyInfo'{}
  issuerUniqueID,      % binary() | asn1_novalue
  subjectUniqueID,     % binary() | asn1_novalue
  extensions           % [#'Extension'{}]}
}.

#'SignatureAlgorithm'{
  algorithm, % id_signature_algorithm()
  parameters % asn1_novalue | #'Dss-Parms'{}
}.
```

id_signature_algorithm() = OID_macro()

The available OID names are as follows:

| OID Name |
|--|
| id-dsa-with-sha1 |
| id-dsaWithSHA1 (ISO or OID to above) |
| md2WithRSAEncryption |
| md5WithRSAEncryption |
| sha1WithRSAEncryption |
| sha-1WithRSAEncryption (ISO or OID to above) |
| sha224WithRSAEncryption |
| sha256WithRSAEncryption |
| sha512WithRSAEncryption |
| ecdsa-with-SHA1 |

Table 2.1: Signature Algorithm OIDs

The data type 'AttributeTypeAndValue', is represented as the following erlang record:

```
#'AttributeTypeAndValue'{
  type,    % id_attributes()
  value    % term()
}.
```

The attribute OID name atoms and their corresponding value types are as follows:

| OID Name | Value Type |
|---------------------------|-----------------------------|
| id-at-name | special_string() |
| id-at-surname | special_string() |
| id-at-givenName | special_string() |
| id-at-initials | special_string() |
| id-at-generationQualifier | special_string() |
| id-at-commonName | special_string() |
| id-at-localityName | special_string() |
| id-at-stateOrProvinceName | special_string() |
| id-at-organizationName | special_string() |
| id-at-title | special_string() |
| id-at-dnQualifier | {printableString, string()} |
| id-at-countryName | {printableString, string()} |
| id-at-serialNumber | {printableString, string()} |
| id-at-pseudonym | special_string() |

Table 2.2: Attribute OIDs

The data types 'Validity', 'SubjectPublicKeyInfo', and 'SubjectPublicKeyInfoAlgorithm' are represented as the following Erlang records:

1.2 Public-Key Records

```
#'Validity'{
  notBefore, % time()
  notAfter   % time()
}.

#'SubjectPublicKeyInfo'{
  algorithm,      % #AlgorithmIdentifier{}
  subjectPublicKey % binary()
}.

#'SubjectPublicKeyInfoAlgorithm'{
  algorithm, % id_public_key_algorithm()
  parameters % public_key_params()
}.
```

The public-key algorithm OID name atoms are as follows:

| OID Name |
|-------------------------|
| rsaEncryption |
| id-dsa |
| dhpublicnumber |
| id-keyExchangeAlgorithm |
| id-ecPublicKey |

Table 2.3: Public-Key Algorithm OIDs

```
#'Extension'{
  extnID,      % id_extensions() | oid()
  critical,    % boolean()
  extnValue    % der_encoded()
}.
```

`id_extensions()` *Standard Certificate Extensions, Private Internet Extensions, CRL Extensions and CRL Entry Extensions.*

1.2.6 Standard Certificate Extensions

The standard certificate extensions OID name atoms and their corresponding value types are as follows:

| OID Name | Value Type |
|------------------------------|-------------------------------|
| id-ce-authorityKeyIdentifier | #'AuthorityKeyIdentifier' { } |
| id-ce-subjectKeyIdentifier | oid() |
| id-ce-keyUsage | [key_usage()] |
| id-ce-privateKeyUsagePeriod | #'PrivateKeyUsagePeriod' { } |
| id-ce-certificatePolicies | #'PolicyInformation' { } |

| | |
|----------------------------------|---------------------------|
| id-ce-policyMappings | #PolicyMappings_SEQOF{ } |
| id-ce-subjectAltName | general_name() |
| id-ce-issuerAltName | general_name() |
| id-ce-subjectDirectoryAttributes | [#Attribute' { }] |
| id-ce-basicConstraints | #BasicConstraints' { } |
| id-ce-nameConstraints | #NameConstraints' { } |
| id-ce-policyConstraints | #PolicyConstraints' { } |
| id-ce-extKeyUsage | [id_key_purpose()] |
| id-ce-cRLDistributionPoints | [#DistributionPoint' { }] |
| id-ce-inhibitAnyPolicy | integer() |
| id-ce-freshestCRL | [#DistributionPoint' { }] |

Table 2.4: Standard Certificate Extensions

Here:

```
key_usage( )
=
    digitalSignature
    | nonRepudiation
    | keyEncipherment
    | dataEncipherment
    | keyAgreement
    | keyCertSign
    | cRLSign
    | encipherOnly
    | decipherOnly
```

And for id_key_purpose():

| OID Name |
|-----------------------|
| id-kp-serverAuth |
| id-kp-clientAuth |
| id-kp-codeSigning |
| id-kp-emailProtection |

1.2 Public-Key Records

| |
|--------------------|
| id-kp-timeStamping |
| id-kp-OCSPSigning |

Table 2.5: Key Purpose OIDs

```

#'AuthorityKeyIdentifier'{
  keyIdentifier,    % oid()
  authorityCertIssuer, % general_name()
  authorityCertSerialNumber % integer()
}.

#'PrivateKeyUsagePeriod'{
  notBefore, % general_time()
  notAfter  % general_time()
}.

#'PolicyInformation'{
  policyIdentifier, % oid()
  policyQualifiers % [#PolicyQualifierInfo{}]
}.

#'PolicyQualifierInfo'{
  policyQualifierId, % oid()
  qualifier          % string() | #'UserNotice'{}
}.

#'UserNotice'{
  noticeRef, % #'NoticeReference'{}
  explicitText % string()
}.

#'NoticeReference'{
  organization, % string()
  noticeNumbers % [integer()]
}.

#'PolicyMappings_SEQOF'{
  issuerDomainPolicy, % oid()
  subjectDomainPolicy % oid()
}.

#'Attribute'{
  type, % oid()
  values % [der_encoded()]
}).

#'BasicConstraints'{
  cA, % boolean()
  pathLenConstraint % integer()
}).

#'NameConstraints'{
  permittedSubtrees, % [#'GeneralSubtree'{}]
  excludedSubtrees  % [#'GeneralSubtree'{}]
}).

#'GeneralSubtree'{
  base, % general_name()
  minimum, % integer()
  maximum % integer()
}).

#'PolicyConstraints'{
  requireExplicitPolicy, % integer()
  inhibitPolicyMapping % integer()
}).

#'DistributionPoint'{
  distributionPoint, % {fullName, [general_name()]} | {nameRelativeToCRLIssuer,
  [#AttributeTypeAndValue{}]}
}

```

1.2 Public-Key Records

```
reasons,          % [dist_reason()]
cRLIssuer         % [general_name()]
}).
```

1.2.7 Private Internet Extensions

The private internet extensions OID name atoms and their corresponding value types are as follows:

| OID Name | Value Type |
|---------------------------|--------------------------|
| id-pe-authorityInfoAccess | ['AccessDescription' {}] |
| id-pe-subjectInfoAccess | ['AccessDescription' {}] |

Table 2.6: Private Internet Extensions

```
#'AccessDescription'{
    accessMethod,    % oid()
    accessLocation   % general_name()
}).
```

1.2.8 CRL and CRL Extensions Profile

Erlang representation of CRL and CRL extensions profile derived from ASN.1 specifications and RFC 5280 are as follows:

```
#'CertificateList'{
    tbsCertList,      % #'TBSCertList{}
    signatureAlgorithm, % #'AlgorithmIdentifier{}
    signature         % bitstring()
}).

#'TBSCertList'{
    version,          % v2 (if defined)
    signature,        % #AlgorithmIdentifier{}
    issuer,           % {rdnSequence, [#AttributeTypeAndValue' {}]}
    thisUpdate,       % time()
    nextUpdate,       % time()
    revokedCertificates, % [#'TBSCertList_revokedCertificates_SEQOF' {}]
    crlExtensions     % [#'Extension' {}]
}).

#'TBSCertList_revokedCertificates_SEQOF'{
    userCertificate,   % integer()
    revocationDate,   % timer()
    crlEntryExtensions % [#'Extension' {}]
}).
```

CRL Extensions

The CRL extensions OID name atoms and their corresponding value types are as follows:

| OID Name | Value Type |
|------------------------------|------------------------------|
| id-ce-authorityKeyIdentifier | ['AuthorityKeyIdentifier {}] |

| | |
|--------------------------------|--|
| id-ce-issuerAltName | {rdnSequence, [#AttributeTypeAndValue'{}]} |
| id-ce-cRLNumber | integer() |
| id-ce-deltaCRLIndicator | integer() |
| id-ce-issuingDistributionPoint | #IssuingDistributionPoint'{'} |
| id-ce-freshestCRL | [#Distributionpoint'{}] |

Table 2.7: CRL Extensions

Here, the data type 'IssuingDistributionPoint' is represented as the following Erlang record:

```
#'IssuingDistributionPoint'{
    distributionPoint,          % {fullName, [general_name()]} | {nameRelativeToCRLIssuer,
    [#AttributeTypeAndValue'{}]}
    onlyContainsUserCerts,      % boolean()
    onlyContainsCACerts,        % boolean()
    onlySomeReasons,            % [dist_reason()]
    indirectCRL,                % boolean()
    onlyContainsAttributeCerts % boolean()
}).
```

CRL Entry Extensions

The CRL entry extensions OID name atoms and their corresponding value types are as follows:

| OID Name | Value Type |
|---------------------------|----------------|
| id-ce-cRLReason | crl_reason() |
| id-ce-holdInstructionCode | oid() |
| id-ce-invalidityDate | general_time() |
| id-ce-certificateIssuer | general_name() |

Table 2.8: CRL Entry Extensions

Here:

```
crl_reason()
=
    unspecified
    | keyCompromise
    | cACompromise
    | affiliationChanged
    | superseded
    | cessationOfOperation
```

1.3 Getting Started

- | certificateHold
- | removeFromCRL
- | privilegeWithdrawn
- | aACompromise

PKCS#10 Certification Request

Erlang representation of a PKCS#10 certification request derived from ASN.1 specifications and RFC 5280 are as follows:

```
#'CertificationRequest'{
    certificationRequestInfo #'CertificationRequestInfo'{},
    signatureAlgorithm      #'CertificationRequest_signatureAlgorithm'{}},
    signature                bitstring()
}

#'CertificationRequestInfo'{
    version      atom(),
    subject      {rdnSequence, [#AttributeTypeAndValue'{}]} ,
    subjectPKInfo #'CertificationRequestInfo_subjectPKInfo'{},
    attributes    [#'AttributePKCS-10' {}]
}

#'CertificationRequestInfo_subjectPKInfo'{
    algorithm #'CertificationRequestInfo_subjectPKInfo_algorithm'{}
    subjectPublicKey bitstring()
}

#'CertificationRequestInfo_subjectPKInfo_algorithm'{
    algorithm = oid(),
    parameters = der_encoded()
}

#'CertificationRequest_signatureAlgorithm'{
    algorithm = oid(),
    parameters = der_encoded()
}

#'AttributePKCS-10'{
    type = oid(),
    values = [der_encoded()]
}
```

1.3 Getting Started

This section describes examples of how to use the Public Key API. Keys and certificates used in the following sections are generated only for testing the Public Key application.

Some shell printouts in the following examples are abbreviated for increased readability.

1.3.1 PEM Files

Public-key data (keys, certificates, and so on) can be stored in Privacy Enhanced Mail (PEM) format. The PEM files have the following structure:

```

<text>
-----BEGIN <SOMETHING>-----
<Attribute> : <Value>
<Base64 encoded DER data>
-----END <SOMETHING>-----
<text>

```

A file can contain several BEGIN/END blocks. Text lines between blocks are ignored. Attributes, if present, are ignored except for Proc-Type and DEK-Info, which are used when DER data is encrypted.

DSA Private Key

A DSA private key can look as follows:

Note:

File handling is not done by the Public Key application.

```

1> {ok, PemBin} = file:read_file("dsa.pem").
{ok,<<"-----BEGIN DSA PRIVATE KEY-----\nMIIBuw"...>>}

```

The following PEM file has only one entry, a private DSA key:

```

2> [DSAEntry] = public_key:pem_decode(PemBin).
[{'DSAPrivateKey',<<48,130,1,187,2,1,0,2,129,129,0,183,
    179,230,217,37,99,144,157,21,228,204,
    162,207,61,246,...>>,
    not_encrypted}]

3> Key = public_key:pem_entry_decode(DSAEntry).
#'DSAPrivateKey'{version = 0,
    p = 12900045185019966618...6593,
    q = 1216700114794736143432235288305776850295620488937,
    g = 10442040227452349332...47213,
    y = 87256807980030509074...403143,
    x = 510968529856012146351317363807366575075645839654}

```

RSA Private Key with Password

An RSA private key encrypted with a password can look as follows:

```

1> {ok, PemBin} = file:read_file("rsa.pem").
{ok,<<"Bag Attribute"...>>}

```

The following PEM file has only one entry, a private RSA key:

```

2> [RSAEntry] = public_key:pem_decode(PemBin).
[{'RSAPrivateKey',<<224,108,117,203,152,40,15,77,128,126,
    221,195,154,249,85,208,202,251,109,
    119,120,57,29,89,19,9,...>>,
    {"DES-EDE3-CBC",<<"kÙeø¼pμL">>}}]

```

In this following example, the password is "abcd1234":

1.3 Getting Started

```
3> Key = public_key:pem_entry_decode(RSAEntry, "abcd1234").
    #'RSAPrivateKey'{version = 'two-prime',
      modulus = 1112355156729921663373...2737107,
      publicExponent = 65537,
      privateExponent = 58064406231183...2239766033,
      prime1 = 11034766614656598484098...7326883017,
      prime2 = 10080459293561036618240...77738643771,
      exponent1 = 77928819327425934607...22152984217,
      exponent2 = 36287623121853605733...20588523793,
      coefficient = 924840412626098444...41820968343,
      otherPrimeInfos = asn1_NOVALUE}
```

X509 Certificates

The following is an example of X509 certificates:

```
1> {ok, PemBin} = file:read_file("cacerts.pem").
{ok,<<"-----BEGIN CERTIFICATE-----\nMIIC7jCCAL"...>>}
```

The following file includes two certificates:

```
2> [CertEntry1, CertEntry2] = public_key:pem_decode(PemBin).
[{'Certificate',<<48,130,2,238,48,130,2,87,160,3,2,1,2,2,
  9,0,230,145,97,214,191,2,120,150,48,13,
  ...>>,
  not_encrypted},
 {'Certificate',<<48,130,3,200,48,130,3,49,160,3,2,1,2,2,1,
  1,48,13,6,9,42,134,72,134,247,...>>,
  not_encrypted}]
```

Certificates can be decoded as usual:

```

2> Cert = public_key:pem_entry_decode(CertEntry1).
#'Certificate'{
  tbsCertificate =
    #'TBSertificate'{
      version = v3, serialNumber = 16614168075301976214,
      signature =
        #'AlgorithmIdentifier'{
          algorithm = {1,2,840,113549,1,1,5},
          parameters = <<5,0>>},
      issuer =
        {rdnSequence,
          [[#'AttributeTypeAndValue'{
            type = {2,5,4,3},
            value = <<19,8,101,114,108,97,110,103,67,65>>]],
          [#'AttributeTypeAndValue'{
            type = {2,5,4,11},
            value = <<19,10,69,114,108,97,110,103,32,79,84,80>>]],
          [#'AttributeTypeAndValue'{
            type = {2,5,4,10},

    #'Extension'{
        extnID = {2,5,29,14},
        critical = false,
        extnValue = [4,20,27,217,65,152,6,30,142|...]},
    #'Extension'{
        extnID = {2,5,29,17},
        critical = false,
        extnValue = [48,24,129,22,112,101,116,101|...]}]},
    signatureAlgorithm =
        #'AlgorithmIdentifier'{
            algorithm = {1,2,840,113549,1,1,5},
            parameters = <<5,0>>},
    signature =
        <<163,186,7,163,216,152,63,47,154,234,139,73,154,96,120,
        165,2,52,196,195,109,167,192,...>>
```

Parts of certificates can be decoded with `public_key:der_decode/2`, using the ASN.1 type of that part. However, an application-specific certificate extension requires application-specific ASN.1 decode/encode-functions. In the recent example, the first value of `rdnSequence` is of ASN.1 type `'X520CommonName'`. (`{2,5,4,3}` = `?id-at-commonName`):

```
public_key:der_decode('X520CommonName', <<19,8,101,114,108,97,110,103,67,65>>).
{printableString,"erlangCA"}
```

However, certificates can also be decoded using `pkix_decode_cert/2`, which can customize and recursively decode standard parts of a certificate:

```
3>{_, DerCert, _} = CertEntry1.
```

```

4> public_key:pkix_decode_cert(DerCert, otp).

        165,2,52,196,195,109,167,192,...>>
```

This call is equivalent to `public_key:pem_entry_decode(CertEntry1)`:

```
5> public_key:pkix_decode_cert(DerCert, plain).
#'Certificate'{ ...}
```

Encoding Public-Key Data to PEM Format

If you have public-key data and want to create a PEM file this can be done by calling functions `public_key:pem_entry_encode/2` and `pem_encode/1` and saving the result to a file. For example, assume that you have `PubKey = 'RSAPublicKey' {}`. Then you can create a PEM-"RSA PUBLIC KEY" file (ASN.1 type 'RSAPublicKey') or a PEM-"PUBLIC KEY" file ('SubjectPublicKeyInfo' ASN.1 type).

The second element of the PEM-entry is the ASN.1 DER encoded key data:

```
1> PemEntry = public_key:pem_entry_encode('RSAPublicKey', RSAPubKey).
{'RSAPublicKey', <<48,72,...>>, not_encrypted}

2> PemBin = public_key:pem_encode([PemEntry]).
<<"-----BEGIN RSA PUBLIC KEY-----\nMEgC...>>

3> file:write_file("rsa_pub_key.pem", PemBin).
ok
```

or:

```
1> PemEntry = public_key:pem_entry_encode('SubjectPublicKeyInfo', RSAPubKey).
{'SubjectPublicKeyInfo', <<48,92,...>>, not_encrypted}

2> PemBin = public_key:pem_encode([PemEntry]).
<<"-----BEGIN PUBLIC KEY-----\nMFw...>>

3> file:write_file("pub_key.pem", PemBin).
ok
```

1.3.2 RSA Public-Key Cryptography

Suppose you have the following private key and a corresponding public key:

- `PrivateKey = #'RSAPrivateKey' {}` and the plaintext `Msg = binary()`

- `PublicKey = #'RSAPublicKey' {}`

Then you can proceed as follows:

Encrypt with the private key:

```
RsaEncrypted = public_key:encrypt_private(Msg, PrivateKey),
Msg = public_key:decrypt_public(RsaEncrypted, PublicKey),
```

Encrypt with the public key:

```
RsaEncrypted = public_key:encrypt_public(Msg, PublicKey),
Msg = public_key:decrypt_private(RsaEncrypted, PrivateKey),
```

Note:

You normally do only one of the encrypt or decrypt operations, and the peer does the other. This normally used in legacy applications as a primitive digital signature.

1.3.3 Digital Signatures

Suppose you have the following private key and a corresponding public key:

- `PrivateKey = #'RSAPrivateKey' {}` or `'DSAPrivateKey' {}` and the plaintext `Msg = binary()`
- `PublicKey = #'RSAPublicKey' {}` or `{integer(), #'DssParams' {}}`

Then you can proceed as follows:

```
Signature = public_key:sign(Msg, sha, PrivateKey),
true = public_key:verify(Msg, sha, Signature, PublicKey),
```

Note:

You normally do only one of the sign or verify operations, and the peer does the other.

It can be appropriate to calculate the message digest before calling `sign` or `verify`, and then use `none` as second argument:

```
Digest = crypto:sha(Msg),
Signature = public_key:sign(Digest, none, PrivateKey),
true = public_key:verify(Digest, none, Signature, PublicKey),
```

1.3.4 Verifying a certificate hostname

Background

When a client checks a server certificate there are a number of checks available like checks that the certificate is not revoked, not forged or not out-of-date.

There are however attacks that are not detected by those checks. Suppose a bad guy has succeeded with a DNS infection. Then the client could believe it is connecting to one host but ends up at another but evil one. Though it is evil, it could have a perfectly legal certificate! The certificate has a valid signature, it is not revoked, the certificate chain is not faked and has a trusted root and so on.

To detect that the server is not the intended one, the client must additionally perform a *hostname verification*. This procedure is described in **RFC 6125**. The idea is that the certificate lists the hostnames it could be fetched from. This

1.3 Getting Started

is checked by the certificate issuer when the certificate is signed. So if the certificate is issued by a trusted root the client could trust the host names signed in it.

There is a default hostname matching procedure defined in **RFC 6125, section 6** as well as protocol dependent variations defined in **RFC 6125 appendix B**. The default procedure is implemented in *public_key:pkix_verify_hostname/2,3*. It is possible for a client to hook in modified rules using the options list.

Some terminology is needed: the certificate presents hostname(s) on which it is valid. Those are called *Presented IDs*. The hostname(s) the client believes it connects to are called *Reference IDs*. The matching rules aims to verify that there is at least one of the Reference IDs that matches one of the Presented IDs. If not, the verification fails.

The IDs contains normal fully qualified domain names like e.g `foo.example.com`, but IP addresses are not recommended. The rfc describes why this is not recommended as well as security considerations about how to acquire the Reference IDs.

Internationalized domain names are not supported.

The verification process

Traditionally the Presented IDs were found in the Subject certificate field as CN names. This is still quite common. When printing a certificate they show up as:

```
$ openssl x509 -text < cert.pem
...
Subject: C=SE, CN=example.com, CN=*.example.com, O=erlang.org
...
```

The example Subject field has one C, two CN and one O part. It is only the CN (Common Name) that is used by hostname verification. The two other (C and O) is not used here even when they contain a domain name like the O part. The C and O parts are defined elsewhere and meaningful only for other functions.

In the example the Presented IDs are `example.com` as well as hostnames matching `*.example.com`. For example `foo.example.com` and `bar.example.com` both matches but not `foo.bar.example.com`. The name `erlang.org` matches neither since it is not a CN.

In case where the Presented IDs are fetched from the Subject certificate field, the names may contain wildcard characters. The function handles this as defined in **chapter 6.4.3 in RFC 6125**.

There may only be one wildcard character and that is in the first label, for example: `*.example.com`. This matches `foo.example.com` but neither `example.com` nor `foo.bar.example.com`.

There may be label characters before or/and after the wildcard. For example: `a*d.example.com` matches `abcd.example.com` and `ad.example.com`, but not `ab.cd.example.com`.

In the previous example there is no indication of which protocols are expected. So a client has no indication of whether it is a web server, an ldap server or maybe a sip server it is connected to. There are fields in the certificate that can indicate this. To be more exact, the rfc introduces the usage of the X509v3 Subject Alternative Name in the X509v3 extensions field:

```
$ openssl x509 -text < cert.pem
...
X509v3 extensions:
    X509v3 Subject Alternative Name:
        DNS:kb.example.org, URI:https://www.example.org
...
```

Here `kb.example.org` serves any protocol while `www.example.org` presents a secure web server.

The next example has both Subject and Subject Alternate Name present:

```
$ openssl x509 -text < cert.pem
...
Subject: C=SE, CN=example.com, CN=*.example.com, O=erlang.org
...
X509v3 extensions:
    X509v3 Subject Alternative Name:
        DNS:kb.example.org, URI:https://www.example.org
...
```

The RFC states that if a certificate defines Reference IDs in a Subject Alternate Name field, the Subject field MUST NOT be used for host name checking, even if it contains valid CN names. Therefore only `kb.example.org` and `https://www.example.org` matches. The match fails both for `example.com` and `foo.example.com` because they are in the Subject field which is not checked because the Subject Alternate Name field is present.

Function call examples

Note:

Other applications like `ssl/tls` or `https` might have options that are passed down to the `public_key:pkix_verify_hostname`. You will probably not have to call it directly

Suppose our client expects to connect to the web server `https://www.example.net`. This URI is therefore the Reference IDs of the client. The call will be:

```
public_key:pkix_verify_hostname(CertFromHost,
                               [{uri_id, "https://www.example.net"}
                               ]).
```

The call will return `true` or `false` depending on the check. The caller do not need to handle the matching rules in the rfc. The matching will proceed as:

- If there is a Subject Alternate Name field, the `{uri_id, string() }` in the function call will be compared to any `{uniformResourceIdentifier, string() }` in the Certificate field. If the two `strings()` are equal (case insensitive), there is a match. The same applies for any `{dns_id, string() }` in the call which is compared with all `{dNSName, string() }` in the Certificate field.
- If there is NO Subject Alternate Name field, the Subject field will be checked. All CN names will be compared to all hostnames *extracted* from `{uri_id, string() }` and from `{dns_id, string() }`.

Extending the search mechanism

The caller can use own extraction and matching rules. This is done with the two options `fqdn_fun` and `match_fun`.

Hostname extraction

The `fqdn_fun` extracts hostnames (Fully Qualified Domain Names) from `uri_id` or other ReferenceIDs that are not pre-defined in the `public_key` function. Suppose you have some URI with a very special protocol-part: `myspecial://example.com`. Since this a non-standard URI there will be no hostname extracted for matching CN-names in the Subject.

To "teach" the function how to extract, you can give a fun which replaces the default extraction function. The `fqdn_fun` takes one argument and returns either a `string()` to be matched to each CN-name or the atom `default` which will invoke the default `fqdn` extraction function. The return value `undefined` removes the current URI from the `fqdn` extraction.

1.3 Getting Started

```
...
Extract = fun({uri_id, "myspecial://"++HostName}) -> HostName;
          (_Else) -> default
          end,
...
public_key:pkix_verify_hostname(CertFromHost, RefIDs,
                               [{fqdn_fun, Extract}])
...

```

Re-defining the match operations

The default matching handles `dns_id` and `uri_id`. In an `uri_id` the value is tested for equality with a value from the `Subject Alternate Name`. If some other kind of matching is needed, use the `match_fun` option.

The `match_fun` takes two arguments and returns either `true`, `false` or `default`. The value `default` will invoke the default match function.

```
...
Match = fun({uri_id, "myspecial://"++A},
            {uniformResourceIdentifier, "myspecial://"++B}) ->
                                     my_match(A,B);
            (_RefID, _PresentedID) ->
                                     default
            end,
...
public_key:pkix_verify_hostname(CertFromHost, RefIDs,
                               [{match_fun, Match}]),
...

```

In case of a match operation between a `ReferenceID` and a `CN` value from the `Subject` field, the first argument to the fun is the extracted hostname from the `ReferenceID`, and the second argument is the tuple `{cn, string()}` taken from the `Subject` field. That makes it possible to have separate matching rules for `Presented IDs` from the `Subject` field and from the `Subject Alternate Name` field.

The default matching transforms the `ascii` values in strings to lowercase before comparing. The `match_fun` is however called without any transformation applied to the strings. The reason is to enable the user to do unforeseen handling of the strings where the original format is needed.

"Pinning" a Certificate

The **RFC 6125** defines *pinning* as:

"The act of establishing a cached name association between the application service's certificate and one of the client's reference identifiers, despite the fact that none of the presented identifiers matches the given reference identifier. ..."

The purpose is to have a mechanism for a human to accept an otherwise faulty Certificate. In for example a web browser, you could get a question like

Warning: you wanted to visit the site www.example.com, but the certificate is for shop.example.com. Accept anyway (yes/no)?"

This could be accomplished with the option `fail_callback` which will be called if the hostname verification fails:

```
-include_lib("public_key/include/public_key.hrl"). % Record def
...
Fail = fun(#'OTPCertificate'{}=C) ->
    case in_my_cache(C) orelse my_accept(C) of
        true ->
            enter_my_cache(C),
            true;
        false ->
            false
    end,
...
public_key:pkix_verify_hostname(CertFromHost, RefIDs,
                                [{fail_callback, Fail}]),
...
```

1.3.5 SSH Files

SSH typically uses PEM files for private keys but has its own file format for storing public keys. The `public_key` application can be used to parse the content of SSH public-key files.

RFC 4716 SSH Public-Key Files

RFC 4716 SSH files looks confusingly like PEM files, but there are some differences:

```
1> {ok, SshBin} = file:read_file("ssh2_rsa_pub").
{ok, <<"----- BEGIN SSH2 PUBLIC KEY ----\nAAAA"...>>}
```

This is equivalent to calling `public_key:ssh_decode(SshBin, rfc4716_public_key):`

```
2> public_key:ssh_decode(SshBin, public_key).
[{#'RSAPublicKey'{modulus = 794430685...91663,
                  publicExponent = 35}, []]}
```

OpenSSH Public-Key Format

OpenSSH public-key format looks as follows:

```
1> {ok, SshBin} = file:read_file("openssh_dsa_pub").
{ok, <<"ssh-dss AAAAB3Nza"...>>}
```

This is equivalent to calling `public_key:ssh_decode(SshBin, openssh_public_key):`

```
2> public_key:ssh_decode(SshBin, public_key).
[{{15642692...694280725,
  #'Dss-Parms'{p = 17291273936...696123221,
               q = 1255626590179665817295475654204371833735706001853,
               g = 10454211196...480338645}},
  [{comment, "dhopsen@VMUbuntu-DSH"}]}]
```

Known Hosts - OpenSSH Format

Known hosts - OpenSSH format looks as follows:

```
1> {ok, SshBin} = file:read_file("known_hosts").
{ok, <<"hostname.domain.com,192.168.0.1 ssh-rsa AAAAB...>>}
```

Returns a list of public keys and their related attributes. Each pair of key and attribute corresponds to one entry in the known hosts file:

1.3 Getting Started

```
2> public_key:ssh_decode(SshBin, known_hosts).
[{'#RSAPublicKey':{'modulus = 1498979460408...72721699,
    publicExponent = 35},
  [{hostnames,["hostname.domain.com","192.168.0.1"]}]},
 {'#RSAPublicKey':{'modulus = 14989794604088...2721699,
    publicExponent = 35},
  [{comment,"foo@bar.com"},
   {hostnames,["|1|BW05qDxk/cFH0wa05JLdHn+j6xQ=|rXQvIxx5cDD3C43k5DPDamawVNA="]}]}]
```

Authorized Keys - OpenSSH Format

Authorized keys - OpenSSH format looks as follows:

```
1> {ok, SshBin} = file:read_file("auth_keys").
{ok, <<"command=\"dump /home\",no-pty,no-port-forwarding ssh-rsa AAA...>>}
```

Returns a list of public keys and their related attributes. Each pair of key and attribute corresponds to one entry in the authorized key file:

```
2> public_key:ssh_decode(SshBin, auth_keys).
[{'#RSAPublicKey':{'modulus = 794430685...691663,
    publicExponent = 35},
  [{comment,"dhopson@VMUbuntu-DSH"},
   {options,["command=\"dump/home\",no-pty",
    "no-port-forwarding"]}]}],
 {{1564269258491...607694280725,
  #'Dss-Parms'{p = 17291273936185...763696123221,
    q = 1255626590179665817295475654204371833735706001853,
    g = 10454211195705...60511039590076780999046480338645}},
  [{comment,"dhopson@VMUbuntu-DSH"}]}]
```

Creating an SSH File from Public-Key Data

If you got a public key `PubKey` and a related list of attributes `Attributes` as returned by `ssh_decode/2`, you can create a new SSH file, for example:

```
N> SshBin = public_key:ssh_encode([PubKey, Attributes], openssh_public_key),
<<"ssh-rsa "...>>
N+1> file:write_file("id_rsa.pub", SshBin).
ok
```

2 Reference Manual

The `public_key` application provides functions to handle public-key infrastructure from RFC 3280 (X.509 certificates) and parts of the PKCS standard.

public_key

Application

Provides encode/decode of different file formats (PEM, OpenSSH), digital signature and verification functions, validation of certificate paths and certificate revocation lists (CRLs) and other functions for handling of certificates, keys and CRLs.

- Supports **RFC 5280** - Internet X.509 Public-Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile. Certificate policies are currently not supported.
- Supports **PKCS-1** - RSA Cryptography Standard
- Supports **DSS** - Digital Signature Standard (DSA - Digital Signature Algorithm)
- Supports **PKCS-3** - Diffie-Hellman Key Agreement Standard
- Supports **PKCS-5** - Password-Based Cryptography Standard
- Supports **PKCS-8** - Private-Key Information Syntax Standard
- Supports **PKCS-10** - Certification Request Syntax Standard

DEPENDENCIES

The `public_key` application uses the `Crypto` application to perform cryptographic operations and the `ASN-1` application to handle PKIX-ASN-1 specifications, hence these applications must be loaded for the `public_key` application to work. In an embedded environment this means they must be started with `application:start/[1,2]` before the `public_key` application is started.

ERROR LOGGER AND EVENT HANDLERS

The `public_key` application is a library application and does not use the error logger. The functions will either succeed or fail with a runtime error.

SEE ALSO

application(3)

public_key

Erlang module

Provides functions to handle public-key infrastructure, for details see *public_key(6)*.

DATA TYPES

Note:

All records used in this Reference Manual are generated from ASN.1 specifications and are documented in the User's Guide. See *Public-key Records*.

Use the following include directive to get access to the records and constant macros described here and in the User's Guide:

```
-include_lib("public_key/include/public_key.hrl").
```

The following data types are used in the functions for public_key:

oid()

Object identifier, a tuple of integers as generated by the ASN.1 compiler.

boolean() =

true | false

string() =

[bytes()]

der_encoded() =

binary()

pki_asn1_type() =

```
'Certificate'
| 'RSAPrivateKey'
| 'RSAPublicKey'
| 'DSAPrivateKey'
| 'DSAPublicKey'
| 'DHParameter'
| 'SubjectPublicKeyInfo'
| 'PrivateKeyInfo'
| 'CertificationRequest'
| 'CertificateList'
| 'ECPrivateKey'
| 'EcpkParameters'
```

pem_entry () =

```
{pki_asn1_type(), binary(), %% DER or encrypted DER
```

```
not_encrypted | cipher_info()
cipher_info() =
  {"RC2-CBC" | "DES-CBC" | "DES-EDE3-CBC", crypto:strong_rand_bytes(8)
  | {'PBEPParameter'}, digest_type()} | {'PBES2-params'}}
public_key() =
  rsa_public_key() | dsa_public_key() | ec_public_key()
private_key() =
  rsa_private_key() | dsa_private_key() | ec_private_key()
rsa_public_key() =
  {'RSAPublicKey'}
rsa_private_key() =
  {'RSAPrivateKey'}
dsa_public_key() =
  {integer(), #'Dss-Parms'}
dsa_private_key() =
  {'DSAPrivateKey'}
ec_public_key()
  = {'ECPoint'}, #'ECParameters' | {namedCurve, oid()}
ec_private_key() =
  {'ECPrivateKey'}
key_params() =
  #'DHParameter' | {namedCurve, oid()} | #'ECParameters' | {rsa, Size::integer(), PubExp::integer()}
public_crypt_options() =
  [{rsa_pad, rsa_padding()}]
rsa_padding() =
  'rsa_pkcs1_padding'
  | 'rsa_pkcs1_oaep_padding'
  | 'rsa_no_padding'
public_sign_options() =
  [{rsa_pad, rsa_sign_padding()} | {rsa_pss_saltlen, integer()}]
rsa_sign_padding() =
  'rsa_pkcs1_padding'
  | 'rsa_pkcs1_pss_padding'
digest_type() =
  Union of rsa_digest_type(), dss_digest_type(), and ecdsa_digest_type().
rsa_digest_type() =
  'md5' | 'ripemd160' | 'sha' | 'sha224' | 'sha256' | 'sha384' | 'sha512'
```

```
dss_digest_type() =  
    'sha' | 'sha224' | 'sha256' | 'sha384' | 'sha512'
```

Note that the actual supported `dss_digest_type` depends on the underlying crypto library. In OpenSSL version `>= 1.0.1` the listed digest are supported, while in 1.0.0 only sha, sha224 and sha256 are supported. In version 0.9.8 only sha is supported.

```
ecdsa_digest_type() =  
    'sha' | 'sha224' | 'sha256' | 'sha384' | 'sha512'
```

```
crl_reason() =  
    unspecified  
    | keyCompromise  
    | cACompromise  
    | affiliationChanged  
    | superseded  
    | cessationOfOperation  
    | certificateHold  
    | privilegeWithdrawn  
    | aACompromise
```

```

    {rdnSequence, [#'AttributeTypeAndValue'{}]}
```

```
ssh_file() =  
    openssh_public_key  
    | rfc4716_public_key  
    | known_hosts  
    | auth_keys
```

Exports

```
compute_key(OthersKey, MyKey) ->  
compute_key(OthersKey, MyKey, Params) ->
```

Types:

```
OthersKey = #'ECPoint'{} | binary(), MyKey = #'ECPrivateKey'{} | binary()  
Params = #'DHParameter'{} 
```

Computes shared secret.

```
decrypt_private(CipherText, Key) -> binary()  
decrypt_private(CipherText, Key, Options) -> binary()
```

Types:

```
CipherText = binary()  
Key = rsa_private_key()  
Options = public_crypt_options()
```

Public-key decryption using the private key. See also *crypto:private_decrypt/4*

```
decrypt_public(CipherText, Key) -> binary()  
decrypt_public(CipherText, Key, Options) -> binary()
```

Types:

```
CipherText = binary()  
Key = rsa_public_key()  
Options = public_crypt_options()
```

Public-key decryption using the public key. See also *crypto:public_decrypt/4*

```
der_decode(Asn1type, Der) -> term()
```

Types:

```
Asn1Type = atom()  
ASN.1 type present in the Public Key applications ASN.1 specifications.  
Der = der_encoded()
```

Decodes a public-key ASN.1 DER encoded entity.

```
der_encode(Asn1Type, Entity) -> der_encoded()
```

Types:

```
Asn1Type = atom()  
ASN.1 type present in the Public Key applications ASN.1 specifications.  
Entity = term()  
Erlang representation of Asn1Type
```

Encodes a public-key entity with ASN.1 DER encoding.

```
dh_gex_group(MinSize, SuggestedSize, MaxSize, Groups) -> {ok, {Size,Group}} |  
{error,Error}
```

Types:

```
MinSize = positive_integer()  
SuggestedSize = positive_integer()  
MaxSize = positive_integer()  
Groups = undefined | [{Size,[{G,P}]}]  
Size = positive_integer()  
Group = {G,P}  
G = positive_integer()  
P = positive_integer()
```

Selects a group for Diffie-Hellman key exchange with the key size in the range `MinSize` . . . `MaxSize` and as close to `SuggestedSize` as possible. If `Groups == undefined` a default set will be used, otherwise the group is selected from `Groups`.

First a size, as close as possible to `SuggestedSize`, is selected. Then one group with that key size is randomly selected from the specified set of groups. If no size within the limits of `MinSize` and `MaxSize` is available, `{error,no_group_found}` is returned.

The default set of groups is listed in `lib/public_key/priv/moduli`. This file may be regenerated like this:

```
$> cd $ERL_TOP/lib/public_key/priv/
$> generate
      ---- wait until all background jobs has finished. It may take several days !
$> cat moduli-* > moduli
$> cd ../; make
```

`encrypt_private(PlainText, Key) -> binary()`

Types:

```
PlainText = binary()
Key = rsa_private_key()
```

Public-key encryption using the private key. See also *crypto:private_encrypt/4*.

`encrypt_public(PlainText, Key) -> binary()`

Types:

```
PlainText = binary()
Key = rsa_public_key()
```

Public-key encryption using the public key. See also *crypto:public_encrypt/4*.

```
generate_key(Params) -> {Public::binary(), Private::binary()} |  
#'ECPrivateKey'{} | #'RSAPrivateKey'{} }
```

Types:

```
Params = key_params()
```

Generates a new keypair. Note that except for Diffie-Hellman the public key is included in the private key structure. See also *crypto:generate_key/2*

`pem_decode(PemBin) -> [pem_entry()]`

Types:

```
PemBin = binary()
Example {ok, PemBin} = file:read_file("cert.pem").
```

Decodes PEM binary data and returns entries as ASN.1 DER encoded entities.

`pem_encode(PemEntries) -> binary()`

Types:

```
PemEntries = [pem_entry()]
```

Creates a PEM binary.

`pem_entry_decode(PemEntry) -> term()`

`pem_entry_decode(PemEntry, Password) -> term()`

Types:

```
PemEntry = pem_entry()
Password = string()
```

Decodes a PEM entry. *pem_decode/1* returns a list of PEM entries. Notice that if the PEM entry is of type 'SubjectPublicKeyInfo', it is further decoded to an *rsa_public_key()* or *dsa_public_key()*.

```
pem_entry_encode(Asn1Type, Entity) -> pem_entry()  
pem_entry_encode(Asn1Type, Entity, {CipherInfo, Password}) -> pem_entry()
```

Types:

```
Asn1Type = pki_asn1_type()  
Entity = term()  
Erlang representation of Asn1Type. If Asn1Type is 'SubjectPublicKeyInfo', Entity must be either an  
rsa_public_key(), dsa_public_key() or an ec_public_key() and this function creates the  
appropriate 'SubjectPublicKeyInfo' entry.  
CipherInfo = cipher_info()  
Password = string()
```

Creates a PEM entry that can be feed to `pem_encode/1`.

```
pkix_decode_cert(Cert, otp|plain) -> #'Certificate'{} | #'OTPCertificate'{}  
Types:
```

```
Cert = der_encoded()
```

Decodes an ASN.1 DER-encoded PKIX certificate. Option `otp` uses the customized ASN.1 specification OTP-PKIX.asn1 for decoding and also recursively decode most of the standard parts.

```
pkix_encode(Asn1Type, Entity, otp | plain) -> der_encoded()  
Types:
```

```
Asn1Type = atom()  
The ASN.1 type can be 'Certificate', 'OTPCertificate' or a subtype of either.  
Entity = #'Certificate'{} | #'OTPCertificate'{} | a valid subtype
```

DER encodes a PKIX x509 certificate or part of such a certificate. This function must be used for encoding certificates or parts of certificates that are decoded/created in the `otp` format, whereas for the plain format this function directly calls `der_encode/2`.

```
pkix_is_issuer(Cert, IssuerCert) -> boolean()  
Types:
```

```
Cert = der_encoded() | #'OTPCertificate'{} | #'CertificateList'{}  
IssuerCert = der_encoded() | #'OTPCertificate'{}  
Checks if IssuerCert issued Cert.
```

```
pkix_is_fixed_dh_cert(Cert) -> boolean()  
Types:
```

```
Cert = der_encoded() | #'OTPCertificate'{}  
Checks if a certificate is a fixed Diffie-Hellman certificate.
```

```
pkix_is_self_signed(Cert) -> boolean()  
Types:
```

```
Cert = der_encoded() | #'OTPCertificate'{}  
Checks if a certificate is self-signed.
```

`pkix_issuer_id(Cert, IssuedBy) -> {ok, IssuerID} | {error, Reason}`

Types:

`Cert = der_encoded() | #'OTPCertificate'{} }`

`IssuedBy = self | other`

`IssuerID = {integer(), issuer_name()}`

The issuer id consists of the serial number and the issuers name.

`Reason = term()`

Returns the issuer id.

`pkix_normalize_name(Issuer) -> Normalized`

Types:

`Issuer = issuer_name()`

`Normalized = issuer_name()`

Normalizes an issuer name so that it can be easily compared to another issuer name.

`pkix_path_validation(TrustedCert, CertChain, Options) -> {ok, {PublicKeyInfo, PolicyTree}} | {error, {bad_cert, Reason}}`

Types:

`TrustedCert = #'OTPCertificate'{} | der_encoded() | atom()`

Normally a trusted certificate, but it can also be a path-validation error that can be discovered while constructing the input to this function and that is to be run through the `verify_fun`. Examples are `unknown_ca` and `selfsigned_peer`.

`CertChain = [der_encoded()]`

A list of DER-encoded certificates in trust order ending with the peer certificate.

`Options = proplists:proplist()`

`PublicKeyInfo = {'rsaEncryption' | '?id-dsa', rsa_public_key() | integer(), 'NULL' | 'Dss-Parms'{} }`

`PolicyTree = term()`

At the moment this is always an empty list as policies are not currently supported.

`Reason = cert_expired | invalid_issuer | invalid_signature | name_not_permitted | missing_basic_constraint | invalid_key_usage | {revoked, crl_reason()} | atom()`

Performs a basic path validation according to **RFC 5280**. However, CRL validation is done separately by `pkix_crls_validate/3` and is to be called from the supplied `verify_fun`.

Available options:

`{verify_fun, fun()}`

The fun must be defined as:

```
fun(OtpCert :: #'OTPCertificate'{},
    Event :: {bad_cert, Reason :: atom() | {revoked, atom()}} |
             {extension, #'Extension'{}},
    InitialUserState :: term()) ->
{valid, UserState :: term()} |
{valid_peer, UserState :: term()} |
{fail, Reason :: term()} |
{unknown, UserState :: term()}.
```

If the verify callback fun returns `{fail, Reason}`, the verification process is immediately stopped. If the verify callback fun returns `{valid, UserState}`, the verification process is continued. This can be used to accept specific path validation errors, such as `selfsigned_peer`, as well as verifying application-specific extensions. If called with an extension unknown to the user application, the return value `{unknown, UserState}` is to be used.

`{max_path_length, integer()}`

The `max_path_length` is the maximum number of non-self-issued intermediate certificates that can follow the peer certificate in a valid certification path. So, if `max_path_length` is 0, the PEER must be signed by the trusted ROOT-CA directly, if it is 1, the path can be PEER, CA, ROOT-CA, if it is 2, the path can be PEER, CA, CA, ROOT-CA, and so on.

Possible reasons for a bad certificate:

`cert_expired`

Certificate is no longer valid as its expiration date has passed.

`invalid_issuer`

Certificate issuer name does not match the name of the issuer certificate in the chain.

`invalid_signature`

Certificate was not signed by its issuer certificate in the chain.

`name_not_permitted`

Invalid Subject Alternative Name extension.

`missing_basic_constraint`

Certificate, required to have the basic constraints extension, does not have a basic constraints extension.

`invalid_key_usage`

Certificate key is used in an invalid way according to the key-usage extension.

`{revoked, crt_reason()}`

Certificate has been revoked.

`atom()`

Application-specific error reason that is to be checked by the `verify_fun`.

`pkix_crl_issuer(CRL) -> issuer_name()`

Types:

`CRL = der_encoded() | #'CertificateList'{}`

Returns the issuer of the CRL.

`pkix_crls_validate(OTPCertificate, DPAndCRLs, Options) -> CRLStatus()`

Types:

```
OTPCertificate = #'OTPCertificate'{}
DPAndCRLs = [{DP::#'DistributionPoint'{}, {DerCRL::der_encoded(),
CRL::#'CertificateList'{}}}]
Options = proplists:proplist()
CRLStatus() = valid | {bad_cert, revocation_status_undetermined} |
{bad_cert, {revocation_status_undetermined, {bad_crls, Details::term()}}}
| {bad_cert, {revoked, crt_reason()}}
```

Performs CRL validation. It is intended to be called from the verify fun of *pkix_path_validation/3*.

Available options:

{update_crl, fun()}

The fun has the following type specification:

```
fun('#DistributionPoint'{}, #'CertificateList'{}) ->
    #'CertificateList'{}

```

The fun uses the information in the distribution point to access the latest possible version of the CRL. If this fun is not specified, Public Key uses the default implementation:

```
fun(_DP, CRL) -> CRL end

```

{issuer_fun, fun()}

The fun has the following type specification:

```
fun('#DistributionPoint'{}, #'CertificateList'{},
    {rdnSequence, [#'AttributeTypeAndValue'{}]}, term()) ->
    {ok, #'OTPCertificate'{}, [der_encoded]}
```

The fun returns the root certificate and certificate chain that has signed the CRL.

```
fun(DP, CRL, Issuer, UserState) -> {ok, RootCert, CertChain}

```

{undetermined_details, boolean()}

Defaults to false. When revocation status can not be determined, and this option is set to true, details of why no CRLs were accepted are included in the return value.

pkix_crl_verify(CRL, Cert) -> boolean()

Types:

```
CRL = der_encoded() | #'CertificateList'{}
Cert = der_encoded() | #'OTPCertificate'{}

```

Verify that Cert is the CRL signer.

pkix_dist_point(Cert) -> DistPoint

Types:

```
Cert = der_encoded() | #'OTPCertificate'{}
DistPoint = #'DistributionPoint'{}

```

Creates a distribution point for CRLs issued by the same issuer as Cert. Can be used as input to *pkix_crls_validate/3*

pkix_dist_points(Cert) -> DistPoints

Types:

```
Cert = der_encoded() | #'OTPCertificate'{}
DistPoints = [#'DistributionPoint'{}]

```

Extracts distribution points from the certificates extensions.

pkix_match_dist_point(CRL, DistPoint) -> boolean()

Types:

```
CRL = der_encoded() | #'CertificateList'{}

```

```
DistPoint = #'DistributionPoint'{} }
```

Checks whether the given distribution point matches the Issuing Distribution Point of the CRL, as described in RFC 5280. If the CRL doesn't have an Issuing Distribution Point extension, the distribution point always matches.

```
pkix_sign(#'OTPTBSCertificate'{}, Key) -> der_encoded()
```

Types:

```
Key = rsa_private_key() | dsa_private_key()
```

Signs an 'OTPTBSCertificate'. Returns the corresponding DER-encoded certificate.

```
pkix_sign_types(AlgorithmId) -> {DigestType, SignatureType}
```

Types:

```
AlgorithmId = oid()
```

Signature OID from a certificate or a certificate revocation list.

```
DigestType = rsa_digest_type() | dss_digest_type()
```

```
SignatureType = rsa | dsa | ecdsa
```

Translates signature algorithm OID to Erlang digest and signature types.

```
pkix_test_data(Options) -> Config
```

```
pkix_test_data([chain_opts()]) -> [conf_opt()]
```

Types:

```
Options = #{chain_type() := chain_opts()}
```

Options for ROOT, Intermediate and Peer certs

```
chain_type() = server_chain | client_chain
```

```
chain_opts() = #{root := [cert_opt()] | root_cert(), peer := [cert_opt()],  
intermediates => [[cert_opt()]]}
```

A valid chain must have at least a ROOT and a peer cert. The root cert can be given either as a cert pre-generated by *pkix_test_root_cert/2*, or as root cert generation options.

```
root_cert() = #{cert := der_encoded(), key := Key}
```

A root certificate generated by *pkix_test_root_cert/2*.

```
cert_opt() = {Key, Value}
```

For available options see *cert_opt()* below.

```
Config = #{server_config := [conf_opt()], client_config := [conf_opt()]}
```

```
conf_opt() = {cert, der_encoded()} | {key, PrivateKey} | {cacerts,  
[der_encoded()]}
```

This is a subset of the type *ssl:ssl_option()*. *PrivateKey* is what *generate_key/1* returns.

Creates certificate configuration(s) consisting of certificate and its private key plus CA certificate bundle, for a client and a server, intended to facilitate automated testing of applications using X509-certificates, often through SSL/TLS. The test data can be used when you have control over both the client and the server in a test scenario.

When this function is called with a map containing client and server chain specifications; it generates both a client and a server certificate chain where the *cacerts* returned for the server contains the root cert the server should trust and the intermediate certificates the server should present to connecting clients. The root cert the server should trust is the one used as root of the client certificate chain. Vice versa applies to the *cacerts* returned for the client. The root cert(s) can either be pre-generated with *pkix_test_root_cert/2*, or if options are specified; it is (they are) generated.

When this function is called with a list of certificate options; it generates a configuration with just one node certificate where `cacerts` contains the root cert and the intermediate certs that should be presented to a peer. In this case the same root cert must be used for all peers. This is useful in for example an Erlang distributed cluster where any node, towards another node, acts either as a server or as a client depending on who connects to whom. The generated certificate contains a subject `altname`, which is not needed in a client certificate, but makes the certificate useful for both roles.

The `cert_opt()` type consists of the following options:

`{digest, digest_type()}`

Hash algorithm to be used for signing the certificate together with the `key` option. Defaults to `sha` that is `sha1`.

`{key, key_params() | private_key()}`

Parameters to be used to call `public_key:generate_key/1`, to generate a key, or an existing key. Defaults to generating an ECDSA key. Note this could fail if Erlang/OTP is compiled with a very old cryptolib.

`{validity, {From::erlang:timestamp(), To::erlang:timestamp()}}`

The validity period of the certificate.

`{extensions, [#'Extension'{}]}`

Extensions to include in the certificate.

Default extensions included in CA certificates if not otherwise specified are:

```
[#'Extension'{extnID = ?'id-ce-keyUsage',
               extnValue = [keyCertSign, cRLSign],
               critical = false},
 #'Extension'{extnID = ?'id-ce-basicConstraints',
               extnValue = #'BasicConstraints'{cA = true},
               critical = true}]
```

Default extensions included in the server peer cert if not otherwise specified are:

```
[#'Extension'{extnID = ?'id-ce-keyUsage',
               extnValue = [digitalSignature, keyAgreement],
               critical = false},
 #'Extension'{extnID = ?'id-ce-subjectAltName',
               extnValue = [{dNSName, Hostname}],
               critical = false}]
```

Hostname is the result of calling `net_adm:localhost()` in the Erlang node where this function is called.

Note:

Note that the generated certificates and keys does not provide a formally correct PKIX-trust-chain and they can not be used to achieve real security. This function is provided for testing purposes only.

`pkix_test_root_cert(Name, Options) -> RootCert`

Types:

Name = `string()`

The root certificate name.

Options = `[cert_opt()]`

For available options see `cert_opt()` under `pkix_test_data/1`.

RootCert = `#{cert := der_encoded(), key := Key}`

A root certificate and key. The `Key` is generated by `generate_key/1`.

Generates a root certificate that can be used in multiple calls to *pkix_test_data/1* when you want the same root certificate for several generated certificates.

`pkix_verify(Cert, Key) -> boolean()`

Types:

```
Cert = der_encoded()
Key = rsa_public_key() | dsa_public_key() | ec_public_key()
```

Verifies PKIX x.509 certificate signature.

`pkix_verify_hostname(Cert, ReferenceIDs) -> boolean()`

`pkix_verify_hostname(Cert, ReferenceIDs, Opts) -> boolean()`

Types:

```
Cert = der_encoded() | #'OTPCertificate'{}
ReferenceIDs = [ RefID ]
RefID = {dns_id,string()} | {srv_id,string()} | {uri_id,string()} |
{ip,inlet:ip_address()|string()} | {OtherRefID,term()}}
OtherRefID = atom()
Opts = [ PvhOpt() ]
PvhOpt = [MatchOpt | FailCallbackOpt | FqdnExtractOpt]
MatchOpt = {match_fun, fun(RefID | FQDN::string(), PresentedID) ->
boolean() | default}
PresentedID = {DNSName,string()} | {uniformResourceIdentifier,string()} |
{iPAddress,list(byte())} | {OtherPresId,term()}}
OtherPresID = atom()
FailCallbackOpt = {fail_callback, fun('#'OTPCertificate'{})) -> boolean()}
FqdnExtractOpt = {fqdn_fun, fun(RefID) -> FQDN::string() | default |
undefined}
```

This function checks that the *Presented Identifier* (e.g hostname) in a peer certificate is in agreement with the *Reference Identifier* that the client expects to be connected to. The function is intended to be added as an extra client check of the peer certificate when performing *public_key:pkix_path_validation/3*

See **RFC 6125** for detailed information about hostname verification. The *User's Manual* and *code examples* describes this function more detailed.

The `{OtherRefId,term() }` is defined by the user and is passed to the `match_fun`, if defined. If that term is a binary, it will be converted to a string.

The `ip` Reference ID takes an *inet:ip_address()* or an ip address in string format (E.g "10.0.1.1" or "1234::5678:9012") as second element.

`sign(Msg, DigestType, Key) -> binary()`

`sign(Msg, DigestType, Key, Options) -> binary()`

Types:

```
Msg = binary() | {digest,binary()}
The Msg is either the binary "plain text" data to be signed or it is the hashed value of "plain text", that is, the digest.
DigestType = rsa_digest_type() | dss_digest_type() | ecdsa_digest_type()
Key = rsa_private_key() | dsa_private_key() | ec_private_key()
```

```
Options = public_sign_options()
```

Creates a digital signature.

```
ssh_decode(SshBin, Type) -> [{public_key(), Attributes::list()}]
```

Types:

```
SshBin = binary()
```

```
Example {ok, SshBin} = file:read_file("known_hosts").
```

```
Type = public_key | ssh_file()
```

If `Type` is `public_key` the binary can be either an RFC4716 public key or an OpenSSH public key.

Decodes an SSH file-binary. In the case of `known_hosts` or `auth_keys`, the binary can include one or more lines of the file. Returns a list of public keys and their attributes, possible attribute values depends on the file type represented by the binary.

RFC4716 attributes - see RFC 4716.

```
{headers, [{string(), utf8_string()}]}
```

`auth_key` attributes - see manual page for `sshd`.

```
{comment, string()}
```

```
{options, [string()]}
```

```
{bits, integer()} - In SSH version 1 files.
```

`known_host` attributes - see manual page for `sshd`.

```
{hostnames, [string()]}
```

```
{comment, string()}
```

```
{bits, integer()} - In SSH version 1 files.
```

```
ssh_encode([Key, Attributes], Type) -> binary()
```

Types:

```
Key = public_key()
```

```
Attributes = list()
```

```
Type = ssh_file()
```

Encodes a list of SSH file entries (public keys and attributes) to a binary. Possible attributes depend on the file type, see *ssh_decode/2*.

```
ssh_hostkey_fingerprint(HostKey) -> string()
```

```
ssh_hostkey_fingerprint(DigestType, HostKey) -> string()
```

```
ssh_hostkey_fingerprint([DigestType], HostKey) -> [string()]
```

Types:

```
Key = public_key()
```

```
DigestType = digest_type()
```

Calculates a ssh fingerprint from a public host key as openssh does.

The algorithm in `ssh_hostkey_fingerprint/1` is md5 to be compatible with older ssh-keygen commands. The string from the second variant is prepended by the algorithm name in uppercase as in newer ssh-keygen commands.

Examples:

```
2> public_key:ssh_hostkey_fingerprint(Key).
"f5:64:a6:c1:5a:cb:9f:0a:10:46:a2:5c:3e:2f:57:84"

3> public_key:ssh_hostkey_fingerprint(md5,Key).
"MD5:f5:64:a6:c1:5a:cb:9f:0a:10:46:a2:5c:3e:2f:57:84"

4> public_key:ssh_hostkey_fingerprint(sha,Key).
"SHA1:bSLY/C4QXLDL/Iwmhyg0PGW9UbY"

5> public_key:ssh_hostkey_fingerprint(sha256,Key).
"SHA256:aZGXhabfbf4oxglxltItWeHU7ub3Dc31NcNw2cMJePQ"

6> public_key:ssh_hostkey_fingerprint([sha,sha256],Key).
["SHA1:bSLY/C4QXLDL/Iwmhyg0PGW9UbY",
 "SHA256:aZGXhabfbf4oxglxltItWeHU7ub3Dc31NcNw2cMJePQ"]
```

`verify(Msg, DigestType, Signature, Key) -> boolean()`

`verify(Msg, DigestType, Signature, Key, Options) -> boolean()`

Types:

Msg = `binary()` | `{digest,binary()}`

The `Msg` is either the binary "plain text" data or it is the hashed value of "plain text", that is, the digest.

DigestType = `rsa_digest_type()` | `dss_digest_type()` | `ecdsa_digest_type()`

Signature = `binary()`

Key = `rsa_public_key()` | `dsa_public_key()` | `ec_public_key()`

Options = `public_sign_options()`

Verifies a digital signature.

`short_name_hash(Name) -> string()`

Types:

Name = `issuer_name()`

Generates a short hash of an issuer name. The hash is returned as a string containing eight hexadecimal digits.

The return value of this function is the same as the result of the commands `openssl crl -hash` and `openssl x509 -issuer_hash`, when passed the issuer name of a CRL or a certificate, respectively. This hash is used by the `c_rehash` tool to maintain a directory of symlinks to CRL files, in order to facilitate looking up a CRL by its issuer name.
